D. J. Bernstein

University of Illinois at Chicago

NSF ITR-0716498

CubeHash is the *smallest* high-security SHA-3 proposal.

Several meanings of “smallest”:

- Smallest memory use.
- Smallest description.
- Smallest code size.
- Smallest vector-code size.
- Smallest area in hardware.

Also good security/speed tradeoff.

Default parameters are

extremely conservative,

but faster-than-MD5 parameters are still resisting all attacks.

Memory use

CubeHash-512 (512-bit output)
fits into 128 bytes of RAM.

Closest competitor:

Keccak; 200 bytes of RAM.

Skein-512: 224 bytes of RAM?

SHA-512: 256 bytes of RAM
(plus counter if necessary).

64 for current state,

64 for beginning-of-block state,

128 for transformed block.

Most submissions: Much larger.

CubeHash b -byte message block
is xor'ed into first b state bytes.
Does *not* take extra space.

Standard generic attacks:
 $2^{512-4b+\text{overhead}}$ bit operations
to find preimages etc.

Default parameter: $b = 1$;
 $2^{508+\text{overhead}}$ bit operations.

$b = 8$ is $\approx 8\times$ faster;
 $2^{480+\text{overhead}}$ bit operations.

$b = 32$ is $\approx 32\times$ faster;
 $2^{384+\text{overhead}}$ bit operations.

Attack details: See submission.

Code size

After b -byte message block,
CubeHash r/b transforms state
(as 32 little-endian 4-byte words)
through r identical rounds.

Finalization: Flip one bit;
 $10r$ extra identical rounds;
output first 64 state bytes.

Initialization: Similarly easy.

SHA-3 proposal: CubeHash8/1;
8 rounds after each byte.

Faster: CubeHash8/2,
CubeHash8/4, CubeHash8/8, etc.

First half of a round:

```
for (i = 0; i < 16; ++i)
    x[i + 16] += x[i];
for (i = 0; i < 16; ++i)
    y[i ^ 8] = x[i];
for (i = 0; i < 16; ++i)
    x[i] = ROTATE(y[i], 7);
for (i = 0; i < 16; ++i)
    x[i] ^= x[i + 16];
for (i = 0; i < 16; ++i)
    y[i ^ 2] = x[i + 16];
for (i = 0; i < 16; ++i)
    x[i + 16] = y[i];
```

Second half of a round:

```
for (i = 0; i < 16; ++i)
    x[i + 16] += x[i];
for (i = 0; i < 16; ++i)
    y[i ^ 4] = x[i];
for (i = 0; i < 16; ++i)
    x[i] = ROTATE(y[i], 11);
for (i = 0; i < 16; ++i)
    x[i] ^= x[i + 16];
for (i = 0; i < 16; ++i)
    y[i ^ 1] = x[i + 16];
for (i = 0; i < 16; ++i)
    x[i + 16] = y[i];
```

Reduced-round cryptanalysis

Traditional confidence-building:
see how many rounds survive
third-party cryptanalysis.

Culmination of attacks by
Aumasson, Brier, Dai, Khazaei,
Meier, Naya-Plasencia, Peyrin:
collision in CubeHash3/64;
 2^{231} for CubeHash5/64.

Do you have an improved attack?
